#### 8. Arrays

- Objectives when we have completed this set of notes, you should be familiar with:
  - array declaration and use
  - bounds checking and capacity
  - arrays that store object references
  - variable length parameter lists
  - multidimensional arrays

 An array is a container object that holds a fixed number of values of a single type.

An array of size N is indexed from zero to N-1

This array holds 10 values that are indexed from 0 to 9

## **Declaring Arrays**

The scores array could be declared as follows:

```
int[] scores = new int[10];
```

- The type of the variable scores is int[] (an array of int or an int array)
- The reference variable scores is set to a new array <u>object</u> that holds 10 integers; note the used of the **new** operator with the size
- The array construct is part of the Java language (whereas ArrayList is a class in the Java class libraries as described in the Java API)

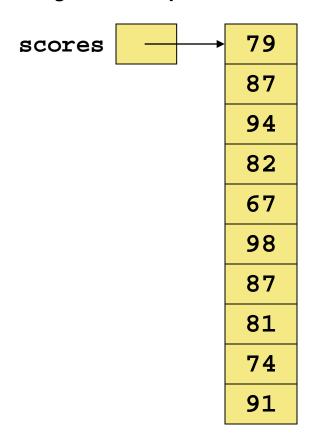

# **Alternate Array Syntax**

 The brackets of the array type can be associated with the element type or with the name of the array:

```
float[] prices;
float prices[];
```

 The first format generally is more readable and should be used

Another way to depict the scores array:

- The values held in an array are called array elements
  - The element type can be a primitive type or a reference type
- The declaration of an array variable does not create the array object; but rather only the variable that will reference it

```
char[] letters;
```

 The new operator creates (or instantiates) the array with the specified number of elements

```
letters = new char[5];
```

- When an array is created, the initial value of each array element depends on the type.
  - Numerical elements (including char) are initialized to 0 or 0.0

```
double[] grades = new double[4];
0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 |
```

boolean values are initialized to false

```
boolean[] statuses = new boolean[3] false false false
```

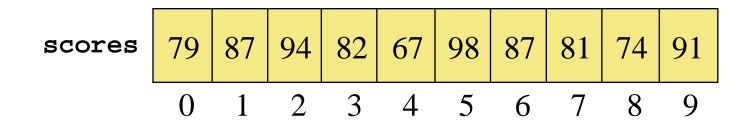

Any type of object element is initialized to null

```
String[] names = new String[2];
Coin[] change = new Coin[4];
CableAccount accounts = new CableAccount[3];
```

ArrayExamples.java

#### **Accessing Array Elements**

- Elements are accessed using the array name followed by the index in brackets
- The expression scores[2] evaluates to the value 94

#### Examples:

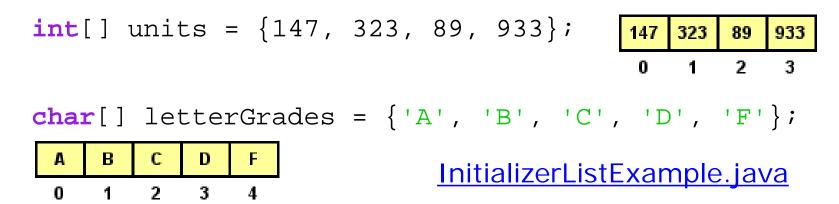

```
int singleScore = scores[2];
System.out.println("3rd score: " + scores[2]);
double avg = ((double) scores[0] + scores[1]) / 2;
```

## **Setting Array Elements**

- Individual array elements are also assigned using the array name followed by the index in brackets
- Example: declare a double array and assign elements

#### **Initializer Lists**

- An initializer list can be used to instantiate and fill an array in one step
  - The size of the array is determined by the number of items in the initializer list
  - It can only be used when declaring the array.
- Examples:

#### **Using Arrays**

 The length variable can be accessed to get the length of the array.

```
int[] scores = new int[10];
scores.length
10
```

The for loop can be used when processing array elements

```
for (int i = 0; i < scores.length; i++) {
   System.out.println (scores[i]);
}</pre>
```

The for each loop can also be used with arrays:

```
for (int currentScore : scores) {
    System.out.println (currentScore);
}
```

#### **Bounds Checking**

- Once an array is created, it has a fixed size
  - An index used in an array reference must specify a valid element from 0 to length - 1
- When a program runs, the Java interpreter throws an ArrayIndexOutOfBoundsException if an array index is out of bounds
- This is called automatic bounds checking
- Common in *off-by-one* errors:

```
for (int i = 0; i <= scores.length; i++) {
   System.out.println (scores[i]);
}</pre>
```

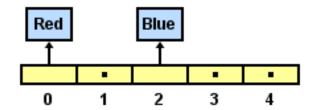

## More on Arrays of Objects

 When the elements of an array are object references, they are initialized to null (i.e., no objects are created).
 For example, below no String objects are created:

```
String[] colors = new String[5];
null value
```

Each object element stored in an array must be instantiated separately

```
colors[2] = new String("Blue");
colors[0] = "Red"; // String objects only
```

#### **Arrays as Parameters**

 An entire array can be passed as a parameter to a method or returned to the client program.

```
public Polygon(double[] sidesIn)
public void setSides(double[] sidesIn)
public double[] getSides()
```

See <u>Polygon.java</u>

#### "Aliases"

- Recall that reference variables can refer to the same object. This was not as important with Strings since they are immutable, but it can cause unexpected results with arrays.
- For example, try the following code in interactions:

```
double[] sides1 = {5.4, 2.3, 5.7, 4.5};
Polygon shape = new Polygon(sides1);
double[] sides2 = shape.getSides();
sides2[0] = -1;
double[] sides3 = shape.getSides();
sides3[0]
-1.0
```

PolygonCheck.java

#### "Aliases"

- Recall that encapsulation is achieved by objects "protecting and managing their own information.
- If you return a reference to an array object (or any object) in a method and it is modified by a client program, does it support encapsulation?
- Lesson: be very careful with reference variables.

# Array vs. ArrayList

- Recall that the size of an array object cannot be changed. Thus, you would have to create a whole new array and copy all of the elements over.
- Similarly, if you want to insert an element into the middle of the array, you'll have to move (copy) the elements to the left to make room
- The ArrayList class holds an array and performs the above operations for you if needed.
- The ArrayList is provided in the Java class library, and so it is unique to the Java language.
   The <u>array</u> is available in all high level languages.

## **Command-Line Arguments**

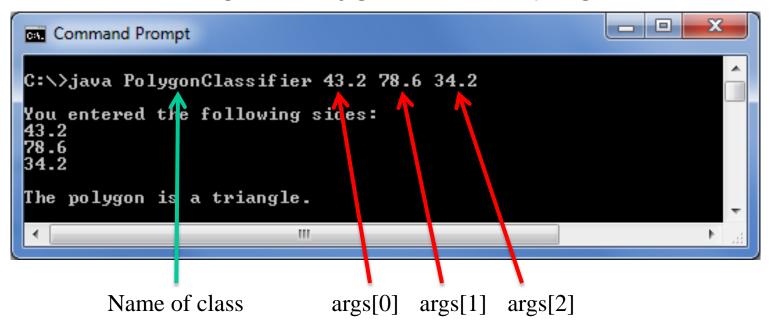

• The signature of the main method indicates that it takes an array of String objects as a parameter

```
public static void main(String[] args)
```

• The args array comes from *command-line arguments* that are provided when the Java interpreter is invoked (for example, in the command prompt or terminal)

## **Command-Line Arguments**

Consider running the PolygonClassifier program:

 For ease of testing your program, command line arguments can also by passed in via jGRASP. See <u>PolygonClassifier.java</u>.

- Suppose we wanted to create a method that processed a different amount of data from one invocation to the next
- For example, let's define a method called average that returns the average of a set of integer parameters

```
// one call to average three values
mean1 = average (42, 69, 37);

// another call to average seven values
mean2 = average (35, 43, 93, 23, 40, 21, 75);
```

- We could define multiple versions of the average method (each taking a different number of parameter inputs)
  - Downside: a separate version of the method would be needed for each parameter count
- We could define the method to accept an array of integers
  - Downside: an array would need to be created and initialized prior to calling the method each time
- Instead, Java provides a convenient way to create a variable length parameter list

- We can define a method to accept any number of parameters of the same type
- The parameters are automatically put into an array with a specified variable name

#### Indicates a variable length parameter list

```
public double average (int ... list)
   double result = 0.0;
   if (list.length != 0) {
      int sum = 0;
      for (int num : list) {
              sum += num;
      result = (double) sum / list.length;
   return result;
```

VariableParams.java

 The type of the parameter can be any primitive type or object type

```
public String allPolygons(Polygon ... polygonSet) {
    String output = "";
    for (Polygon shape : polygonSet) {
        output += shape + " ";
    }
    return output;
}
```

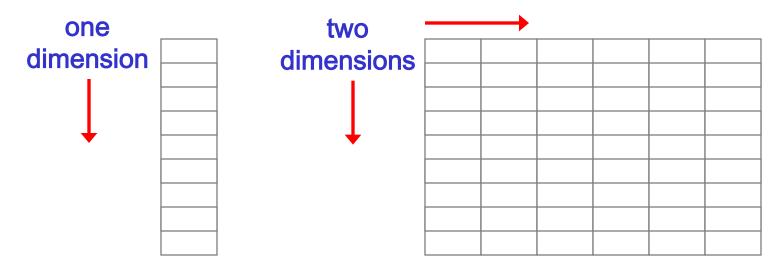

- A method that accepts a variable number of parameters can also accept other parameters
- The following method accepts an int, a String object, and a variable number of double values into an array called nums

```
public void test(int count, String name, double ... nums)
```

- The variable number of parameters must come last in the formal arguments
- A single method cannot accept two sets of varying parameters
- Constructors can also be set up to accept a variable number of parameters
- See Family.java in the book.

## **Two-Dimensional Arrays**

- A one-dimensional array stores a list of elements
- A two-dimensional array can be thought of as a table of elements, with rows and columns

#### **Two-Dimensional Arrays**

- A two-dimensional array is an "array of arrays"
- A two-dimensional array is declared by specifying the size of each dimension separately:

```
int[][] scores = new int[12][50];
```

 A single element is referenced using two index values:

```
int value = scores[3][6];
```

The array stored in one row can be specified using one index

```
int[] valueSet = scores[3];
```

# **Two-Dimensional Arrays**

Expression	Type	Description
table	int[][]	2D array of integers, or
		array of integer arrays
table[5]	int[]	array of integers
table[5][12]	int	integer

• See <u>TwoDArraySums.java</u>

#### Multidimensional Arrays

- An array can have many dimensions if it has more than one dimension, it is called a multidimensional array
- Because each dimension is an array of array references, the arrays within one dimension can be of different lengths
  - these are sometimes called ragged arrays
